

Red and White Wine Explorer Dashboard vs. AI

Colin Hui

The two dashboard images above explore the Wine Quality dataset, which includes data of detailed chemical properties and quality scores for a total of 6,497 wines: 1,599 red and 4,898 white. My dashboard on the left which was developed using Python and the Holoviz Panel, allows users to interactively filter the data by wine type, alcohol percentage, and quality range. The dashboard first features a dynamic scatterplot of alcohol vs. quality, and the other tabs provide a bar chart of quality score distributions, and a tabulated view of the filtered data with an additional option to download the results as a CSV file. These tools allows and empowers users to explore the relationships between alcohol content and perceived wine quality while easily isolating specific subsets of the data. However, when looking at the AI-generated dashboard on the right which was created using Claude, it clearly emphasizes aesthetics and quick insight delivery. It initially displays comparative bar charts for red and white wines, while also including a visually polished interface with tabs for overview and analysis, as well as summary metrics like total wine count and the full quality range. Although Claude's version offers a faster and more presentation-ready design, my custom-coded dashboard provides more granular control, transparency, and flexibility for exploratory data analysis. However, I would say that both of these dashboards highlight the key insights of aspects such as the prevalence of quality scores between 5 and 6 and even the larger proportion of white wines. Though, I found the hands-on coding process offered deeper understanding and confidence in the data. All in all, while the AI-generated version excels in aspects such as visual appeal and speed of development, I would say that the custom-coded dashboard offers greater analytical depth and trustworthiness.
